

# Maxila, Mandíbula e Dentes

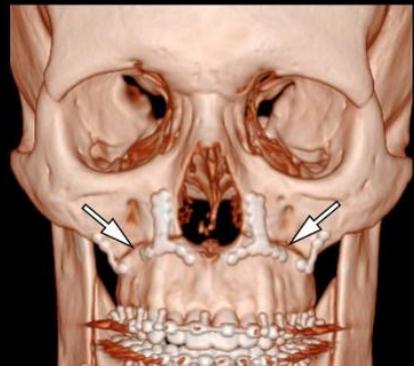

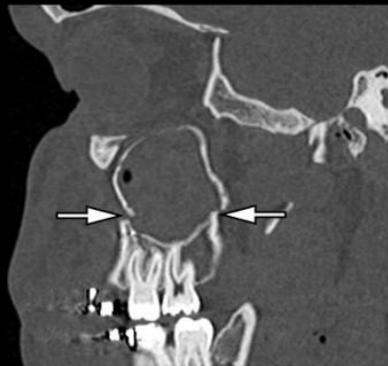

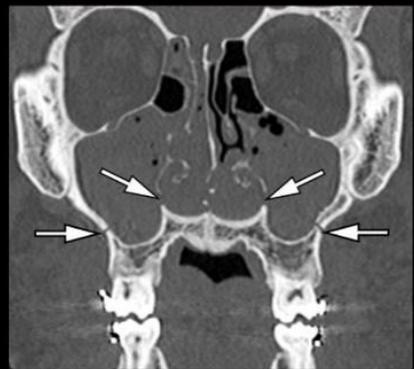

## Cirurgia ortognática

A cirurgia ortognática é um conjunto de osteotomias realizadas na maxila e/ou na mandíbula para corrigir deformidades dentofaciais. As principais técnicas são:

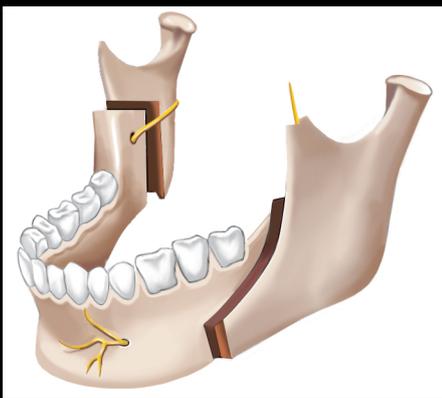

### Osteotomia Le Fort I

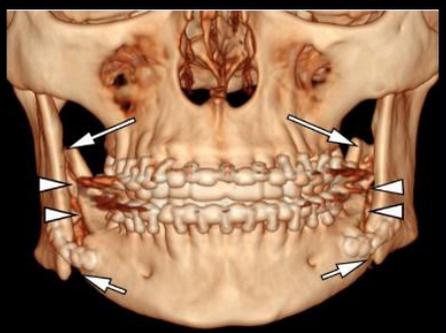

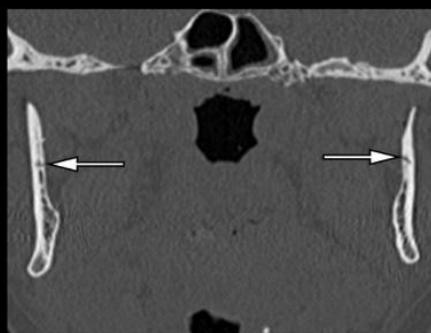

Osteotomia horizontal acima dos ápices dos dentes superiores envolvendo a abertura piriforme, os seios maxilares e o septo nasal, poupando as lâminas dos processos pterigoides, de modo que a região inferior da maxila fique livre para ser reposicionada.

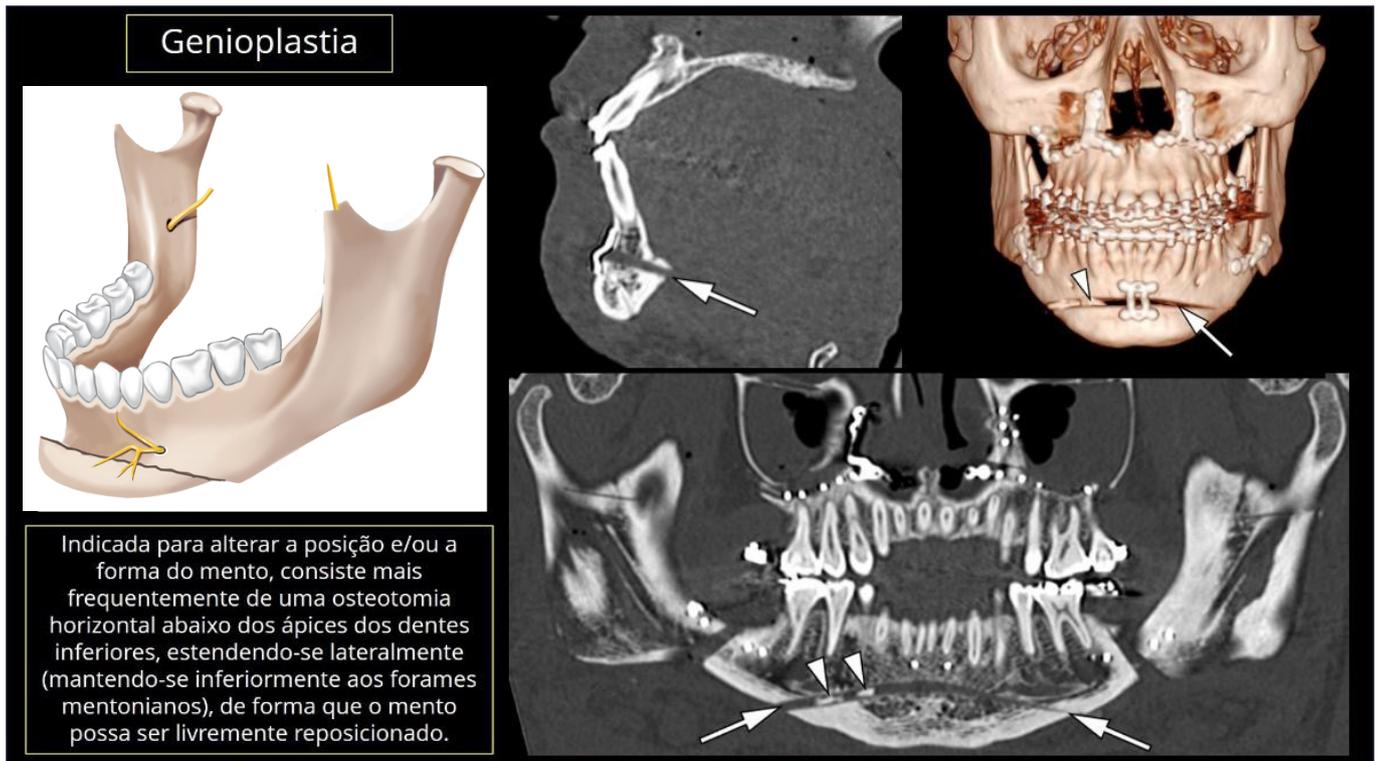

### Osteotomia Sagital Mandibular Bilateral

Osteotomias nos ramos, ângulos e região posterior dos hemicorpos mandibulares, de modo que o segmento distal (mais anterior) fique livre para ser reposicionado.
